

ProSlimelt® - Melts Away Fat with Ultrasound

I have now been working in the field of anti-aging for the last 10 years and have been repeatedly asked for help by my patients in eliminating fatty areas of their bodies and in improving their figures. The classical treatment to remove fat deposits, liposuction, is often a good method to deal with these figure problems. Unfortunately, this procedure must be performed under anesthesia and involves incisions, pain and possible side effects.

I was really surprised when I heard about an innovative method for the first time which utilizes a special ultrasound device to “melt away” fat deposits, and this without causing pain or the need for a surgical procedure.

I first thought that “this couldn’t be possible.”

But as unbelievable as it initially sounded, the method really does work and does so in an outstanding way. The underlying physical principles of this technology have been known for a long time, but the technical preconditions for successful routine use have only recently been provided by an innovative ultrasound device (**ProSlimelt®**). The technology utilizes special low frequency ultrasonic shock waves to produce so-called acoustic cavitation effects to cause fat cells in the subcutaneous fat tissues of the problem areas to implode and thus destroys them. The imploded fat cells and the remaining fat residues are dissolved by the body’s own natural mechanisms, then transported away by the lymph system and are finally excreted.

Microscopic Pictures Before and After Treatment

Fat deposits cannot form again where there are no fat cells!

This new ultrasonic technology simply melts away the fat deposits and does so without pain, bleeding, the risk of infection or other risks.

The treatment of a problem area such as the abdomen, buttocks, hips, thighs etc. only takes 1 hour, and immediately thereafter, a clear reduction in the body part circumference of a few centimeters can be seen. This positive effect becomes even more noticeable in the days following the treatment as the destroyed fat cells are gradually dissolved. Several treatments at weekly intervals are required to eliminate larger fat deposits. The variable adjustment settings of the ultrasonic device enable individual adjustment of the unit to adapt it to the tissue structure of each patient and to thus eliminate the risk of the formation of dents in the tissue. A positive side effect is that the treatment does produce a change in the skin structure and can thus help patients to relieve their cellulitis.

As with conventional liposuction, the ultrasonic method also has only limited effectivity in treating extreme obesity. The primary application field for this new technology is body contouring through the reduction of fat deposits in the problem zones.

Proslimelt® Ultrasound Device

The fat melting treatment is similar to an ultrasound examination by your family doctor. The desired treatment zone is coated with ultrasound gel, and the transducer is moved slowly over the skin without causing pain. No massaging is done with the **ProSlimelt®** device – neither the skin surface nor the subcutaneous fatty tissues are pulled or rolled, and the skin is not subjected to suction. The patient can stand up directly after the treatment and proceed with his/her normal activities. Of course, it makes sense to reexamine one's own eating habits and, if necessary, to optimize them so that fat deposits do not reoccur at other parts of the body. In summary, I can say that it is extremely astonishing, even for a specialist, to see how effectively and simply this innovative technology produces the desired results.

Melt fat away with:

- The latest ultrasound technology
- No anesthesia
- Nonsurgical procedure
- Painless
- No risks or scars
- Visible improvements after each treatment

In any case, the first successfully treated patients are extremely happy with this new method of body contouring and are enthusiastic about their new figure!
